Experiments showed that the transfer of chromium atoms in any solvent metal takes place at a considerably greater rate in the grain boundary portions. The self-diffusion of chromium also proceeds preferentially along grain boundaries. The coefficients of self-diffusion of chromium for temperatures of 1100, 1200 and 1350°C were calculated, and the activation energy of the process (Q) was also determined separately for grain bodies and grain boundaries. For grain bodies $Q = 76\ 000$, and for the boundaries $Q = 46\ 00$ cal/g·atm.
